### ABSTRACT

**الأهداف:** التعرف على الخصائص السريرية والمخبرية لمرض COVID-19 في العينة الخاضعة للدراسة من الأطفال السعوديين في وجود عدوى COVID-19 المؤكدة عن طريق اختبار ال PCR.

**المنهجية:** اشتملت هذه الدراسة على 88 طفلاً (0-14 عاماً) تم استقباليهم والتشخيص اعتماداً على نتيجة إيجابية لاختبار COVID-19 في مدينة الأمير سلطان الطبية العسكرية بالرياض في الفترة من أبريل إلى يونيو 2020م.

**النتائج:** أظهرت هذه الدراسة أن متوسط العمر كان 5.74 سنة؛ واشتملت على 41 (49.4%) ذكور و 42 (50.6%) إناث. تراوحت مدة التنويم بالمستشفى من يوم إلى 17 يوماً. وكان المصدر الرئيسي للعدوى هو أفراد الأسرة. كانت القيم المتوسطة ل CRP و Ferritin و LDH أعلى بشكل ملحوظ عن المعدل الطبيعي. ارتبطت درجة الشدة ومدة التنويم ارتباطاً عكسياً بعدد كرات الدم البيضاء للمفاوية ( $r = -0.36$ ,  $p = 0.001$ )، في حين كانت مرتبطة بشكل طردي مع ارتفاع مؤشرات الالتهاب، مثل Ferritin، D-Dimer، ESR، CRP، مستويات LDH و INR.

**الخلاصة:** يمكن استنتاج أن تحديد الخصائص السريرية والمخبرية للأطفال السعوديين المصابين بفيروس كوفيد-19 المؤكد سيحسن فهم عرض هذا المرض الذي بدوره سيساعد في وضع استراتيجيات إدارة سريعة ومناسبة لمواجهة هذا الوباء. هناك حاجة لارتفاع مؤشر الاشتباه في الحالات المصابة بمرض الالتهاب متعدد الأجهزة والذي يمثل 5.7% من مجتمع الدراسة المشمول.

**Objectives:** To identify clinical and laboratory characteristics of the Saudi children with confirmed COVID-19.

**Methods:** Eighty-eight children (0-14 years) with COVID-19 who were admitted to Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia from April to June 2020 were recruited.

**Results:** Mean age was  $5.74 \pm 4.7$  years with 41 (49.4%) males and 42 (50.6%) females. The length of hospital stay (LOS) ranged from 1 to 17 days. The main source of infection was infected family members. Mean values of C-reactive protein (CRP), serum ferritin, and lactate dehydrogenase (LDH) were noticeably above normal. Degree of severity and length of stay was significantly correlated with lymphopenia ( $r = -0.36$ ;  $p = 0.001$ ),

whereas it was positively correlated with absolute neutrophil count and with high inflammatory markers, such as CRP, LDH, and others.

**Conclusions:** Identifying the clinical and laboratory characteristics of the Saudi children with confirmed COVID-19 will improve understanding of this disease's presentation and will help put rapid and proper management strategies into place to face this pandemic. A high index of suspicion is needed for cases presenting with multi-system inflammatory disease, which represented 5.7% of the included study population.

**Keywords:** COVID-19, children, Saudi Arabia, pediatric, Multisystem inflammatory disease, MIS-c.

On December 31, 2019, a “viral pneumonia of unknown nature” was first stated in Wuhan, China, which was originally named the “2019 Novel Coronavirus” (2019-nCoV). Two months later 2020, the International Committee on Taxonomy of Viruses denoted that the new coronavirus is capable of infecting humans as Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2). Thereafter, the World Health Organization (WHO) had announced the official

name of the illness caused by this virus as COVID-19. As of March 4, 2020, there have been 93,094 confirmed cases of COVID-19 in 77 countries, with 80,422 cases in China.<sup>1</sup> COVID-19 is a worldwide health crisis. The clinical aspects, disease progress, and outcome in children and young adults appear to be less severe than in older individuals. Since then, COVID-19 has spread rapidly, where more than 200 countries suffered this pandemic. Until that time, pediatric patients account for 1-5% of diagnosed COVID-19 cases.<sup>2</sup> Mortality in children appears to be uncommon. Fever and cough are consistent features of COVID-19 in children, although infected children appear to be asymptomatic, they may play a role to transmission of infection.<sup>3</sup> It remains unclear why children and young adults have milder disease course than older people; however, it might include changes in the immune system function in the elderly or changes either in the expression or the function of the cell receptors for SARS-CoV2 namely Angiotensin Converting Enzyme 2 (ACE2).<sup>3,4</sup> Fever and respiratory symptoms should not be considered as the only mark of COVID-19 in children. Many other viral or bacterial infections share a common manifestation with COVID-19. Therefore, pediatricians should have a high index of suspicion to diagnose children with SARS-Cov-2 especially with asymptomatic or mild cases. Irrespective of the promising prognosis, it is significant for the children's role in the contamination cycle to be accurately determined and managed carefully.<sup>5</sup> The disease has affected many parts of Saudi Arabia so far, with over 100,000 established cases and a reported case fatality rate of 0.73%.<sup>6</sup> Inflammation is a crucial part of a functioning immune response. It is problematic to eradicate infections effectively without inflammation. However, SARS-CoV-2 produces severe and prolonged cytokine and chemokine responses in some patients, which are named cytokine storms, which lead to acute respiratory distress syndrome (ARDS) or multiple organ dysfunction, and eventually deterioration and death. Methods of regulating the cytokine storm include immune-modulators and cytokine inhibitors, as well as reducing the lung infiltration by inflammatory cells. Declining the mortality rate of patients with COVID-19 is achieved through proper control of the cytokine storm in its initial stage.<sup>7</sup> Available data suggest that children may have more upper rather than

lower respiratory tract infection. There is also a concern about fecal to oral transmission of the virus due to evidenced shedding of the virus in the stool for many weeks after diagnosis, which points to viral replication in the gastrointestinal tract.<sup>7,8</sup> The Centers for Disease Control (CDC) state Kawasaki Disease as an illness in a patient with fever for 5 or more days along with the presence of at least 4 of the following 5 clinical signs: rash, cervical lymphadenopathy (at least 1.5 cm in diameter), bilateral conjunctival injection, oral mucosal changes, and peripheral extremity changes.<sup>9</sup>

Direct detection of SARS-CoV-2 from a patient with multi-inflammatory systemic (MIS-C) disease in children might suggest its role in the disease presentation. As the COVID-19 pandemic outgrows over time, the presence of the specific SARS-CoV-2 antibody alone may be insufficient to explain the exact pathogenesis in which COVID-19 evokes an unusual immunological response leading to MIS-C.<sup>10,11</sup>

The aim of this study is to identify the clinical and laboratory characteristics of Saudi children with confirmed COVID-19, which could help to increase the awareness among pediatricians about this new virus and help establish rapid and appropriate management strategies to face this pandemic, especially in the near future, when an increased number of cases is expected in the fall.

**Methods.** This retrospective study recruited 88 children admitted to Prince Sultan Military Medical City (PSMMC), Riyadh, Saudi Arabia during a period of 3 months from April to June 2020. Children aged between 4 days and 14 years with a confirmed COVID-19 diagnosis were included in the study. Data were collected by the patients' primary care team and plotted in an Excel sheet. Confirmed COVID-19 cases were defined as patients with suspected COVID-19 who tested positive in a polymerase chain reaction (RT-PCR) analysis for SARS-CoV-2 through a nasopharyngeal swab in accordance with international testing guidelines, irrespective of clinical signs and symptoms. Clinical and laboratory data of the included patients were collected by carefully reviewing the patients' files.

The study was approved by the internal research board (number 1348, June 23, 2020). Each subject was given a study code number with no use of any identifiers. Data security was assured and maintained by the principal investigator. All data (both soft and hard copies) were maintained and saved within the PSMMC premises and accessed by the research team only.

Laboratory and radiological workup were guided by the Saudi Ministry of Health (MOH) protocol and

**Disclosure.** Authors have no conflict of interests, and the work was not supported or funded by any drug company.

individualized according to the case severity. As of that time, the protocol recommended that patients who require hospital admission should be assessed properly and then daily for either thrombotic or bleeding risk. Laboratory work up include: baseline complete blood count (CBC), fibrinogen, prothrombin time (PT), activated partial thromboplastin time (aPTT), D-dimer. Baseline imaging are not recommended in case there is no clinical symptoms suggestive of venous embolism.<sup>5</sup>

Inclusion criteria were children of ages 0 to 14 years, confirmed Covid-19 by RT-PCR, and admittance to

PSMMC from April to the end of June 2020. Exclusion criteria was children clinically suspected of COVID-19 infection with negative RT-PCR results.

**Statistical analysis.** Data were processed using Statistical Package for Social Sciences version 17 (SPSS Inc., Chicago, IL). The normality of the quantitative data distribution was examined using the D'Agostino-Pearson test. Parametric quantitative variables are presented as mean ± SD. Intergroup differences was compared using a student's t-test. Non-parametric numerical variables are expressed as median (interquartile range). Categorical variables are shown as numbers (percentages). Correlation studies were tested parametrically using the Pearson product moment correlation coefficient (PPMCC) or non-parametrically using the Spearman rank correlation as appropriate. Statistical significance is considered for *p*-value <0.05.

**Results.** Our study was conducted with a total of 88 children who had confirmed COVID-19 infection. The main group constituted 83 patients who presented with uncomplicated course while only 5 of the 88 children had a complicated course in the form of MIS-C. The main group's mean age was 5.74 (4.7) years, and there were 41 (49.4%) males and 42 (50.6%) females. The length of hospital stay (LOS) ranged from 1 to 17 days. The epidemiological and clinical characteristics of the studied population are summarized in **Table 1**. The values of the main laboratory findings for the principle group are summarized in **Table 2**. The frequency of the children

**Table 2** - Laboratory findings of the studied population (N=83).

Variables	Mean (SD)
White blood cell (10 <sup>9</sup> /l)	7.89 (3.66)
Hb (g/dl)	12.06 (2.38)

*Procalcitonin (ng/ml)	0.08 (0.04- 0.30)

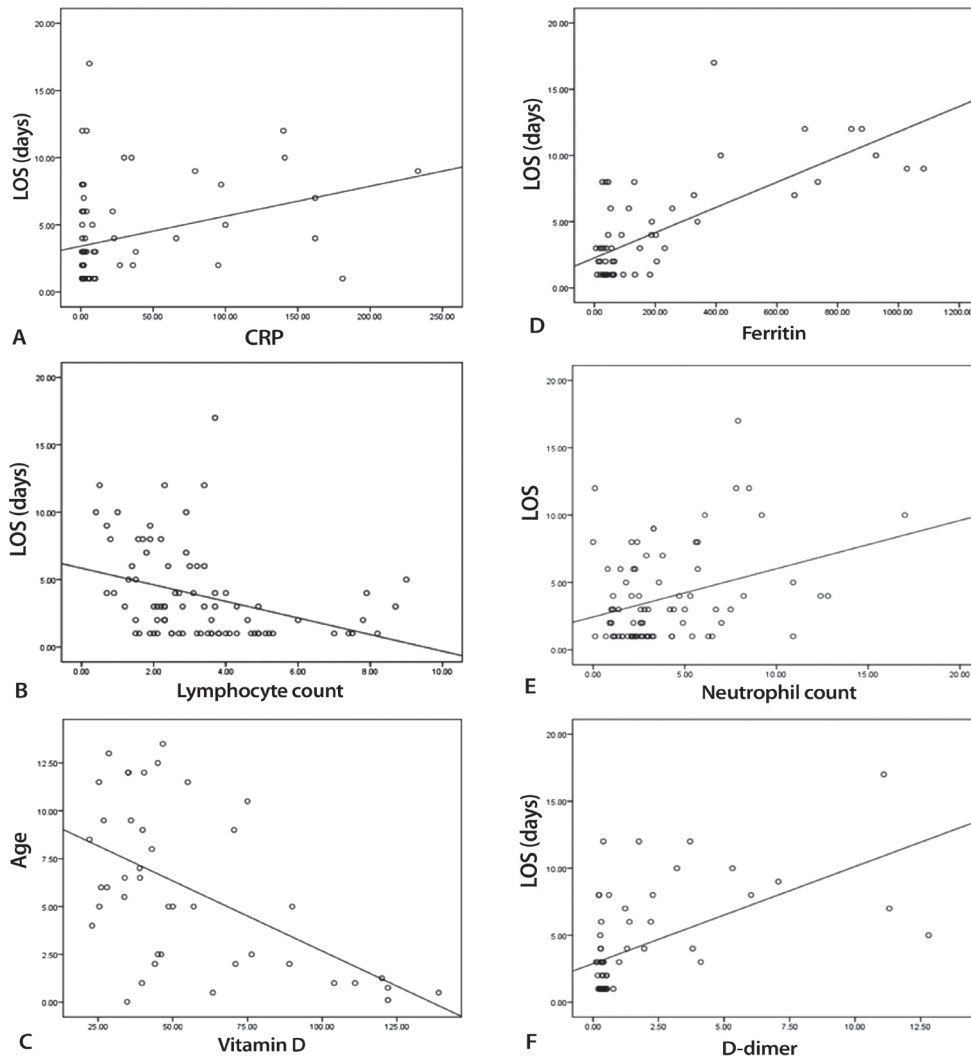

\*Data are presented as Median (25<sup>th</sup> -75<sup>th</sup> interquartile range)

**Table 3** - Leukocytes and inflammatory markers in studied population.

Laboratory parameter	Frequency (%)
Leucopenia (white blood cell <4 10 <sup>9</sup> /l)	15/83 (18)
Lymphopenia (lymphocytes <2 10 <sup>9</sup> /l)	18/83(21.7)
Neutropenia (neutrophils <1 10 <sup>9</sup> /l)	6/83(7.2)
Neutrophilia (neutrophils >9.5 10 <sup>9</sup> /l)	5/83(6)
Leukocytosis (WBC >20 10 <sup>9</sup> /l)	0/83
Vitamin D <50 nmol/l	25/42 (59.5)
High Ferritin (>124 ng/ml)	24/61 (39.3)
D-dimer (>0.5 ug/ml)	24/62 (38.7)
Procalcitonin > 0.05 ng/ml	30/48 (62.5)

having abnormal CBC and inflammatory markers is illustrated in **Table 3**. Leukopenia and lymphopenia were encountered in approximately 20% of the study group, whereas high ferritin and high D-dimer levels were encountered in 40%. Approximately 60% were found to have vitamin D levels below normal levels, which was not correlated with the outcome of the disease.

The correlation studies revealed a significant negative correlation between age and vitamin D levels ( $r = -0.54$ ,  $p \leq 0.001$ ). Length of hospital stay was significantly negatively correlated with lymphocyte count ( $r = -0.36$ ,

**Figure 1** - Correlation between the length of stay and the different inflammatory markers as well as vitamin D level. A) CRP, B) lymphocyte count, C) vitamin D, D) ferritin, E) neutrophil count and F) D-dimer.

$p=0.001$ ), but it was positively correlated with absolute neutrophil count and high inflammatory markers such as C-reactive protein (CRP), erythrocyte sedimentation rate (ESR), D-dimer, ferritin, lactate dehydrogenase (LDH), and INR levels ( $r=0.33$ ,  $p=0.002$ ,  $r=0.31$ ,  $p=0.007$ ,  $r=0.35$ ,  $p=0.03$ ,  $r=0.57$ ,  $p\leq 0.001$ ,  $r=0.72$ ,  $p<0.001$ ,  $r=0.35$ ,  $p=0.01$ ,  $r=0.30$ ,  $p=0.01$ , respectively; **Figure 1**). Vitamin D levels were significantly low in children with hypoxia ( $p=0.002$ ), but no significant associations were observed in cases presenting with cough ( $p=0.623$ ) and diarrhea ( $p=0.672$ ).

The data showed that our study population could be divided into 2 main groups based on the presence or absence of comorbidities. Their laboratory and clinical findings are compared in **Table 4**. There were 49 (59%) recruited children who had underlying comorbidities in addition to COVID-19 infection. Increased levels of D-dimer ( $p=0.023$ ), the presence of cough ( $p=0.005$ ), and distress ( $p=0.017$ ) were associated with the presence of comorbidities. A non-significant difference ( $p=0.236$ ) was found between the presence of underlying comorbidity and other parameters, as shown in **Table 4**.

There were 5 (5.7%) sick children with severe disease who presented with MIS-C. Their ages ranged between 8 and 12 years, there were 4 boys and 1 girl, and they all presented with fever, distress, hypoxia, malaise, dehydration, skin rash, dry lips, abdominal pain, bilateral chest x-ray infiltrations, and variable tachycardia. They were all positive for SARS-CoV-2 IgG

and IgM. Blood and urine cultures showed no growth, which ruled out the possibility of concomitant bacterial infection. Echocardiography showed normal cardiac function with no coronary dilatation. They all received a treatment protocol consisting of a combination of IVIG, pulse steroids, aspirin/antiplatelet medication, and antibiotics. They fully recovered after an average of 10 days of hospitalization.

**Discussion.** Early in the pandemic, there were small number of reported cases of COVID-19 in children, but as time elapsed, more cases were recognized. Little is known about this disease, which has broad-spectrum clinical presentations ranging from asymptomatic to death. However, it is reassuring that children have a relatively smooth course of the disease in comparison to adults, despite few reported deaths in otherwise healthy children.<sup>12</sup>

We hereby described the main clinical, laboratorial, and radiological characteristics of 88 children infected with SARS-CoV-2 admitted to our hospital during the period of April to June 2020. We encountered increasing numbers of cases, especially in May 2020 after the easing of curfew hours and re-opening of shopping malls. We noticed that affected family members, namely the mothers (49.4%) and fathers (26.5%), were the main source of infection for these children. It is clear from our study that boys (49.4%) and girls (50.6%) are equally infected with SARS-CoV-2.

**Table 4** - Clinical and laboratory characteristics in children with and without underlying comorbidities.

Variable	Absence of comorbidity N=34	Presence of comorbidity N=49	P-value
Length of stay (days)*	3.48 (2.1)	4.26 (3.4)	0.312
White blood cell ( $10^9/l$ )*	7.62 (3.2)	8.28 (4.1)	0.424
Lymphocytes ( $10^9/l$ )*	3.49 (1.8)	3.04 (2.1)	0.303
Neutrophils ( $10^9/l$ )*	3.49 (2.5)	4.25(3.8)	0.286
C-reactive protein (mg/l)*	48.07 (31.7)	49.96 (18.9)	0.276
Procalcitonin (ng/ml)†	0.08 (0.03-0.22)	0.14 (0.05-0.3475)	0.353
D-dimer (ug/ml)†	0.37 (0.030-0.53)	0.76 (0.37-3.77)	0.023
Ferritin (ng/ml)†	262.09 (154.4)	307.08 (265.1)	0.143
Ill looking children‡	30 (88.2)	48 (97.9)	0.118
Fever‡	21 (61.7)	32 (65.3)	0.679
Cough‡	9 (26.4)	20 (40.8)	0.005
Distress‡	2 (5.8)	9 (18.3)	0.017

\*Values are presented as mean (SD), †Values are expressed as median (25<sup>th</sup> – 75<sup>th</sup> interquartile range),

‡Values are presented as number and percentage (%).

The main clinical presentations were fever (63.9%), mild cough (32.5%), diarrhea (27.7%), and malaise (34.9%). Pulmonary infiltration was mild and non-specifically detected in 24.1%, whereas hypoxia was only encountered in 8.4% of children. All the included patients had favorable outcomes and smooth recovery. This agrees with what has been published before in studies from China. Dong et al<sup>8</sup> reported in his study on 2,143 children with COVID-19 that the clinical aspects of children were relatively less severe than those of adult patients. According to published data, fever is the most common sign in children, followed by dry cough.<sup>8,12,13</sup> Other symptoms of the different system affection such as respiratory tract, gastrointestinal tract, muscular and nervous systems, and fatigue were also reported, while some other kids were asymptomatic.<sup>8,11,12,13</sup>

Regarding moderate to severe cases, hypoxia and dyspnea could occur which required various modes of respiratory support. Acute respiratory distress syndrome (ARDS) and life-threatening multiple-organ failure has been reported in a few critical cases.<sup>8</sup> Looking at the laboratory findings in the study population, leucopenia were present in 18/83 (21.7%) and lymphopenia in 15/83 (18%) cases, while neutropenia were present in only 7% and neutrophilia in 6%. Inflammatory markers like CRP were increased to 4 times their normal values in 18/76 (23.6%) cases, while procalcitonin was mildly elevated up to 2 ng/ml in 31% without concomitant bacterial infection.

Henry et al<sup>14</sup> found similar findings when summarizing 12 studies on 66 children with reported normal leucocyte counts (69.2%), neutropenia (6%), neutrophilia (4.6%), and lymphopenia (3%). C-reactive protein were high in only 13.6% and procalcitonin in 10.6% of cases. Following the lymphocyte count and CRP is advised as a sign of the severity of infection, potential bacterial co-infection could be ruled out by checking the procalcitonin levels.

It is not well known whether SARS-CoV-19 infection adds a risk for thrombosis during critical illness in children, but statements in adults suggest a prothrombotic tendency.<sup>15,16</sup> In our study, the average D-dimer level was 0.4 (0.30-1.37) ug/ml. It is used in one of the laboratories workups for risk assessment of venous thrombo-embolism (VTE) in hospitalized patients with COVID-19. Zang et al suggested that D-dimer of 2.0 ug/ml on admission might be the proper cutoff to predict the in-hospital mortality for adults with COVID-19, since mortality rate was significantly higher in those patients with D-dimer  $\geq$ 2.0 ug/ml than those with lower levels.<sup>15</sup> No cutoff value for D-dimer has been determined for the severity of infection in children, so we recommend following up the dimer

level and correlation with the daily clinical status of hospitalized children to detect any risk of thrombosis.

Surprisingly, 25/42 (59.5%) of the included population was deficient in vitamin D with levels below 50 nmol/L according to the American Academy of Pediatrics' (AAP's) definition of vitamin D deficiency.<sup>17</sup> Although this low level did not affect the outcome of infection, considering the well-known benefits of vitamin D on the health of children, they would benefit from vitamin D supplementation even before being infected, and vitamin D could have a positive effect in the course of the disease if children become infected later on. We agree with Martineau and Forouhi that vitamin D might also lower the impact of COVID-19 in populations where vitamin D deficiency is common and that there is no loss from giving vitamin D to those populations.<sup>18</sup>

This study included 41 (49.4%) children with underlying comorbidities such as sickle cell disease, syndromic patients with global developmental delay, leukemia, Behcet disease, congenital heart disease, and prematurity. These children showed more severe illness that required hospitalization and the initiation of medications like antiviral drugs and prophylactic anti-thrombotics (low-molecular-weight heparin). This included high-risk patients for thrombosis who were ill and admitted to pediatric intensive care in addition to needing empirical antibiotics from the very beginning of admission. Increased level of D-dimer ( $p=0.023$ ), cough ( $p=0.005$ ), and distress ( $p=0.017$ ) were significantly associated with comorbidities. However, there was no statistically significant difference with  $p>0.05$  in outcomes or other laboratory results. They all responded well and picked up in few days with complete recovery without any clinical or laboratory evidence of VTE. These are similar findings to those of DeBiasi et al,<sup>19</sup> who compared SARS-CoV-2-infected patients who were non-critically ill and those who were critically ill and hospitalized. There were no significant differences in the presence of underlying conditions overall or any specific underlying diagnosis.

We observed that only a small proportion (5/88) of infected children were severely sick and required PICU admission, mainly due to hypoxemia and cytokine storm or MIS-C. High inflammatory markers and chest infiltration were very characteristic in addition to severe abdominal pain. All of them were previously healthy children and were infected with COVID-19 approximately 4 to 6 weeks prior to presenting with MIS-C. Initial echocardiography was normal with no coronary dilatation. All patients were under close observation in the intensive care unit. The outcomes were very promising with no mortality.

The literature describing SARS-CoV-2 infection causing severe illness and COVID-19 in children is minimal but expanding by time.<sup>20</sup> Multi-inflammatory systemic often occurs 1-6 weeks following infection and may overlap with the acute respiratory manifestations of acute COVID-19.<sup>19,21</sup> It can also complicate with coronary artery aneurysms and other extra-cardiac manifestations consistent with Kawasaki disease. Another reported evidence of multi-organ failure, neurologic involvement, hyperferritinemia, and cardiogenic or shock. As well as significant GI manifestations on presentation, such as vomiting, diarrhea, and severe abdominal pain.<sup>22</sup>

**Study limitations.** The relatively small sample size and follow up of the patients laboratories and immune status could not be achieved due to pandemic precautions.

In conclusion, COVID-19 was announced to be a global health emergency in March 2020. COVID-19 is less severe in children than adults and has a wide range of disease severity from asymptomatic to severely ill, which progresses to MIS-C. Most of the children had mild symptoms, and most of them did not require hospital admission, although they can potentially infect others. As time elapses, there will be more reports of MIS-C worldwide, which should raise the awareness of pediatricians about the serious complications of SARS-Cov2.

Early identification of cases, proper and timely management, applying preventive measures, as well as vaccine development are the keys to control the disease spread. A high index of suspicion is required for all sick children to detect Kawasaki-like or hyper inflammatory syndrome. Further large-scale studies on MIS-C are highly encouraged to identify the spectrum of the disease, different biomarkers that predict severity, and the best treatment options.

**Acknowledgment.** *The authors would like to express their appreciation to our colleagues in the infectious diseases and infection control who were always working hard during the pandemic to protect us and to prevent the spread of infection.*
