Case Report

Recurrent maturing perineal lipoblastoma

Hashem M. Al-Momani, MSc, FRCS.

ABSTRACT

Lipoblastoma is a rare benign neoplasm of fetal adipose tissue that we see mostly in infants and young children less than 3 years of age. Most lipoblastomas occur on the extremities, trunk, head and neck, and various other organs have been described. We report a case of a recurrent perineal lipoblastoma in a 2.5-year-old boy, which showed maturation of the lipoblasts as compared to the primary tumor.

Case Report. A 2.5-year-old boy was referred to us for a perineal swelling, which was first noticed and excised at the age of one. The histopathology then was consistent with lipoblastoma (Figure 1); the swelling recurred and increased in size progressively to a size of 8 × 6 cm. It was soft in consistency with the previous scar seen to the left of the midline (Figure 2); otherwise, the patient was completely healthy with no sphincter problem for both urinary and stool. A CT-scan showed a mass encroaching on the anorectal canal more to the left side, and its density was suggestive of lipoma. The mass was well encapsulated and excised completely through an anterior sagittal incision; the mass was attached to the external anal sphincter posteriorly but not infiltrating it; and close to the urethra anteriorly. Microscopically, the histology as compared to the previous slides, showed maturation of the lipoblastoma (Figure 3). The patient recovered uneventfully postoperatively. He was seen 6 months later free of recurrence, with a nicely healed scar and with intact anal and urinary sphincteric control.

Discussion. Lipoblastoma is a rare tumor of infancy and early childhood. It was first described by Jaffe in 1926;¹ and since then many cases were reported; Chung and Enzinger, in 1973, suggested the term benign lipoblastoma for the circumscribed type, and the term benign lipoblastomatosis for the diffuse multicentric type of this neoplasm.² Lipoblastomas occur mainly in the extremities, other less common sites include the trunk, neck,

These tumors have a high tendency for local recurrence of 14-33% as reported in the literature, especially in deeply seated and infiltrative types of lipoblastomatosis, where total excision without destroying major structures is difficult. In the present case the patient was free from recurrence for 6 months, but he requires longer follow up as there are reports of tumor recurrence in 2 cases 6 and 8 years postoperatively.

The histopathology of recurrent tumor shows a continuous maturation into a mature lipoma, this fact is also supported by the continuous maturation of the lipoblasts into adipocytes seen on retroperitoneum and the chest; whereas the perineum is very rare with only 2 cases previously reported in the literature.

In the present case, the patient had a perineal lipoblastoma without any other abnormality especially in the external genitalia; as compared to the other 2 cases of perineal lipoblastoma reported in the literature; describing a bifid scrotum and genital ambiguity. Complete surgical excision; but not radical cancer-type surgery, is the treatment of choice as these tumors are benign and with no reports of metastasis, and radical surgery might be mutilating in children. The prognosis in these tumors is excellent, despite their potential for local recurrence. One case reports spontaneous resolution of the tumor.

The ultimate diagnosis depends on the histological examination of the excised tumor. We found good correlation between the histological and cytological findings in the fine needle aspiration material, but a lipoblastoma diagnosis must be established only after careful consideration of all available clinical and radiological data to be differentiated from lipoma with regressive changes and myxoid liposarcoma. These tumors have a high tendency for local recurrence of 14-33% as reported in the literature, especially in deeply seated and infiltrative types of lipoblastomatosis, where total excision without destroying major structures is difficult. In the present case the patient was free from recurrence for 6 months, but he requires longer follow up as there are reports of tumor recurrence in 2 cases 6 and 8 years postoperatively.
